## **GLUE v. 2.0 – Reference Realization to JSON Schema**

### **Status of This Document**

This document provides information to the community regarding the GLUE 2.0 JSON schema. Distribution is unlimited.

### **Copyright Notice**

Copyright © Open Grid Forum (2014, 2016). All Rights Reserved.

### **Abstract**

The GLUE 2 specification [1] is an information model for Grid entities described in natural language enriched with a graphical representation using UML Class Diagrams. This document presents a realisation of this information model as JSON [2] and formally describes this realization using JSON Schema [4].

## 1. About this Document

The GLUE 2.0 Information model defined in [1] is a conceptual model of Grid entities. In order to be adopted by technology providers, a realisation in terms of a concrete data model is needed. This document provides the normative realisation of the GLUE 2.0 conceptual model in terms of a JSON Schema [4,5]. The document also elaborates on the design choices adopted to map the entities and relationships of the conceptual model into the concrete data model.

This document is maintained by OGF's GLUE Working Group, which signs responsible for documenting errata and releasing revisions as defined by the OGF document process. Errors and feedback in general should be directed to the GLUE WG mailing list, at <glue-wg@ogf.org>.

## 2. Notational Conventions

The key words 'MUST,' "MUST NOT," "REQUIRED," "SHALL," "SHALL NOT," "SHOULD," "SHOULD NOT," "RECOMMENDED," "MAY," and "OPTIONAL" are to be interpreted as described in [rfc -2119].

## 3. JSON

JSON is a lightweight textual format for exchanging structured information that was originally derived from JavaScript. However, JSON is independent of JavaScript and its use has spread widely. JSON is formally defined in [3].

JSON is a simple language with only two complex types: Objects that specify key/value pairs and arrays that specify ordered lists of values. The values in these complex types can themselves be complex types or they can be a string or a number. This simple structure makes it very easy to map JSON documents to structures in many different programming languages.

## 4. JSON Schema

JSON was defined and became popular before it had a formal language to describe the structure of specific classes of JSON documents. An effort called JSON Schema was formed to address this by submitting several draft versions of their schema specification to the IETF. The current version at the time of this writing is draft 04 [5,6] and this document uses that version.

A JSON Schema document constrains the hierarchy of a conforming JSON (instance) document in terms of objects and arrays. It can also describe the required names in objects, the types of values in object attribute values, the types of values in arrays, and constrain possible values (e.g. a value must be from a set of possible values). In addition, JSON Schema allows human-readable descriptions to be embedded into the schema specifications, allowing a schema author to provide in-line documentation.

There are a variety of JSON Schema validators available in different programming languages (see the JSON Schema website for suggestions). This allows projects to add JSON Schema validation to their software infrastructure if they so desire.

## 5. JSON Schema Realisation

### 5.1 Namespaces

The Open Grid Forum has provided guidelines for uniquely identifying uniform names in the GGF/OGF domain [ogf-ns]. Based on this document, we have adopted the following

namespace for the JSON Schema realization of GLUE 2.0:

GLUE-JSON-NS ::= 'http://schemas.ogf.org/glue/' YYYY '/' MM '/spec\_' M.N '\_r' R '/' ENTITYNAME'.json'

YYYY: year of the normative document of the GLUE specification

MM: month of the normative document of the GLUE specification

M.N: M is the major version and N is the minor version of the GLUE conceptual model

R: component to be used to specify the revision number of the JSON realization; this number SHOULD be incremented each time a new non-backwards compatible version is published

ENTITYNAME: represents the name of the GLUE entity in the JSON document; every conceptual entity/class has corresponding JSON realisation

As a non-normative example, the namespace for the first release of the JSON document for Entity of the final GLUE 2.0 specification [glue-2] is:

[http://schemas.ogf.org/glue/2014/11/spec\\_2.0\\_r1/Entity.json](http://schemas.ogf.org/glue/2014/11/spec_2.0_r1/Entity.json)

## 5.2 Schema as a Set of JSON Documents

The GLUE2 JSON Schema is specified using a set of schema documents [7] with each GLUE 2 Entity having its own document. JSON Schema allows schema documents to be composed. We took this approach for easier comprehension and because separate entity schema documents may be of use to those using document-oriented databases to store GLUE 2 JSON documents.

The **Glue2.json** schema document is the aggregating root document containing the major entities, and should be used to validate full GLUE 2 JSON documents. This document, partially shown in Figure 1, defines an object with keys that are named after the GLUE 2 Entities and values that are arrays of GLUE 2 Entity objects. These Entity objects are referred to by id and are specified in separate JSON Schema files. All of the entities are arrays because even though some Entities occur at most once per site or per grid, a GLUE 2 document could describe multiple sites or grids.

```
{
  "$schema": "http://json-schema.org/draft-04/schema#",
  "id": "http://schemas.ogf.org/glue/2014/11/spec_2.0/Glue2.json",
  "description": "A GLUE 2 document",
  "type": "object",
  "properties": {
    "Entity": {
      "type": "array",
      "items": {
        "type": "object",
        "allOf": [{"$ref":
"http://schemas.ogf.org/glue/2014/11/spec_2.0/Entity.json"}]
      }
    },
    "Location": {
      "type": "array",
      "items": {
        "type": "object",
        "allOf": [{"$ref":
"http://schemas.ogf.org/glue/2014/11/spec_2.0/Location.json"}]
      }
    },
    ...
  }
}
```

Figure 1. Partial Glue2.json top-level schema definition file.

### 5.3 GLUE 2 JSON Flat Document Structure

The top-level schema approach described above leads to a flat document structure where the different GLUE 2 Entities are equal siblings defined at the same level of nesting. This is similar to the structure adopted in the GLUE 2 XML rendering [9]. There are a number of functional justifications for adopting a flat document structure compared to deeply nesting entities into parent-child relationships. These are fully explained in the GLUE 2 XML rendering document [9] and will only be summarised here:

- The GLUE 2 information model is not a strict tree structure. Entities with multiple parents and many-to-many relationships cannot be represented by nesting alone. Conversely, representing associations using ID references alone produces no such limitations.
- Nesting entities defines a strong parent-child relationship, where the lifespan of the child is strongly linked to that of the parent (UML composition). However, the entity relationships in GLUE 2 represent weaker UML aggregations where entities can exist in isolation with their own independent life spans. This is better suited to the ID referencing.
- Data can be 'sliced' more easily for use in projection queries (i.e. queries that require that only selected entities are returned).
- The loose coupling provided by ID references allows query results to be split across multiple JSON documents. For example, one document could provide a list of service endpoints whilst another could provide contact information. This allows potentially sensitive information to be split into different documents.

A partial example of this flat structure is shown below with full examples available at [8].

```
{
  "ComputingEndpoint": [

Figure 2. Example GLUE2 document (condensed).

## 5.4 Representing GLUE 2 Entities in JSON

As shown in the example above, each GLUE 2 entity is mapped to a JSON object using the same level of nesting within the document. The keys of an entity object match the names of attributes defined for that entity in the GLUE 2 specification.

The values in the entity objects are based on the GLUE 2 specification. If an entity attribute can have at most one value, a simple value is used in the JSON document. If an entity attribute can have more than one value, an array is used in the JSON document, even if only one value is present in a specific document.

Two important details to clarify are how associations and enumerations are represented.

### 5.4.1 Associations

In the conceptual model, several association types are represented. They can be classified in terms of the multiplicity (one-to-one, one-to-many), in terms of the navigability (bi-directional, unidirectional) or in terms of the association type (binary, aggregation, composition, association class).

Associations between entities are represented using ID keys and references to those IDs. Each entity has a unique ID specified in the 'ID' key. Associations are then specified by referencing the IDs of other entities inside an 'Associations' object. For example, in Figure 2 above, the ComputingService has an ID of 'urn:glue2:ComputingService:stampede.tacc.xsede.org' and the ComputingShare references this value in the ServiceID key. This means that the ComputingShare is associated with the specific ComputingService. Note that the keys used to refer to other entities have names that end in the suffix 'ID', such as 'ServiceID' in this example.

Following the pattern established in the GLUE 2 XML rendering [9], entities in the JSON schema reference other entities using keys named after the parents of the referenced entities, rather than defining more specialized keys named directly after the referenced entity. For example, we use 'EndpointID' to reference a computing endpoint and not 'ComputingEndpointID' (in this case, Endpoint is the parent of ComputingEndpoint so we use 'EndpointID'). This caters for a well-defined use case: standard queries can be executed on a document irrespective of the subtype of the referenced entity (i.e. facilitating a polymorphic query).

The Schema allows associations to be represented bidirectionally. For example, as shown above, a ComputingEndpoint can reference its computing service using a 'ServiceID' key. On the other side of the relationship, the ComputingService references its computing endpoints using an EndpointID key. This bidirectional representation can be convenient in some situations and inconvenient in other situations.

To ensure that every association is represented, at least one direction of each association is required in the schema. This approach also makes interoperability easier because a consumer can look for the association direction that the schema requires.

The directions that are required were selected using the heuristics:

- In the case of a many-to-one association, “the many” refer to “the one”.
- In the case of a one-to-one association:
  - The entity that is created/deleted more often refers to the entity that is created/deleted less often.
  - If the entities that are created/deleted at the same rate, they refer to each other in a bidirectional manner.

Examples of these recommendations in practice are shown in Figure 2.

Many ComputingShares refer to one ComputingService, so the ComputingShares are required to use their ServiceID to refer to the ID of the ComputingService.

A Location is rarely deleted (or never is), so the ComputingService refers to the Location using a LocationID attribute.

The ComputingManager and ComputingService entities are created and deleted at the same rate, so the ComputingManager refers to the ComputingService using a ServiceID attribute and the ComputingService refers to the ComputingManager using a ManagerID attribute.

It can occur that an association direction is required, but there is no association to represent. In this case, the value of the association is either the JSON null value (when the association is one-to-one) or an empty array (when the association is one to many). The empty arrays under Associations in Figure 2 are an example of this.

#### 5.4.2 Enumerations

In the conceptual model, the enumerations are defined using a set of strings. They are categorised as: ‘open’ enables applications to append the existing enumerations, ‘closed’ restricts the use of the existing enumerations.

Closed enumerations are specified using the JSON schema `enum` keyword. Figure 3 shows the `QualityLevel` enumeration from the `Service.json`. JSON schema validators will ensure that the value provided for this key in the JSON document is one of the strings specified in the enumeration.

```

"Service": {
  ...
  "QualityLevel": {
    "type": "string",
    "description": "QualityLevel_t",
    "enum": ["development", "pre-production", "production", "testing"]
  },
  ...
}

```

Figure 3: Example of a close enumeration

One of our design choices is to embed the closed enumerations into the entities instead of defining them separately and referring to them by id. We choose this approach to improve readability of the schemas. A few of the enumerations are used by more than one entity which leads to multiple places to update when an enumeration changes, but the values in the closed enumerations rarely change. Alternative options are:

- Define closed enumerations separately and refer to them in entities
  - This hurts readability
- Embed closed enumerations that are only used once, refer to separately defined enumerations if they are used by several entities
  - This is an inconsistent method and would also hurt readability

For the open enumerations, there is no JSON schema validation that can be performed because any value is valid. In this case, the value is a simple string and the description

associated with it refers to the name of the open enumeration type. The recommended values for the enumerations are given in the GLUE v 2.0 specification. Figure 4 shows how the Type attribute of a Service is specified as a string, but the human-readable description references the open enumeration ServiceType\_t. Section B.31 of the GLUE v 2.0 specification lists the set of values that have already been defined for this enumeration.

```
"Service": {  
  ...  
  "Type": {  
    "type": "string",  
    "description": "ServiceType_t (open enumeration)"  
  },  
  ...  
}
```

Figure 4: An open enumeration

## 5.5 Extending the GLUE 2 JSON Schema

By default, additional properties are allowed in JSON schema. Extension could be prevented by specifying 'additionalProperties: false' so that only the keys specified for an object would be allowed. If any other keys were present, validation would fail. However, the value of additionalProperties cannot be overridden by an extending JSON schema object and so we do not use this feature as we wish to support extension.

During document validation, it is important to note the following; JSON schema validators only check that required keys are present and that their values are valid against the schema. If a JSON object has keys that aren't specified in its corresponding object schema, they are simply ignored.

A provider of a GLUE 2 JSON document MAY include additional, arbitrary JSON content in the Extension object that are present in all entities. This content will not be validated against a schema.

A provider of a GLUE 2 JSON document SHOULD NOT include additional, arbitrary JSON content outside of Extension. As described above, this JSON schema ignores additional object attributes.

If a provider wishes to extend the GLUE 2 JSON Schema, they should define their own entities that extend the entities described in the schema and then define their own variant of Glue2.json that includes their entities along with unmodified GLUE 2 JSON Schema entities.

## 6. Security Considerations

Security considerations related to the GLUE information model are discussed in section 9 of the GLUE specification [glue-2]. Additional considerations apply to the use of XML – for those, see [rfc-3470].
